## Motivation

## Motivation

Data analytics problems in various disciplines can often be simplified to nonsmooth composite convex minimization problems. To this end, this lecture provides efficient numerical solution methods for such problems.

Intriguingly, composite minimization problems are far from generic nonsmooth problems and we can exploit individual function structures to obtain numerical solutions nearly as efficiently as if they are smooth problems.

## Composite convex minimization

## Problem (Unconstrained composite convex minimization)

$$
\begin{equation*}
F^{\star}:=\min _{\mathbf{x} \in \mathbb{R}^{p}}\{F(\mathbf{x}):=f(\mathbf{x})+g(\mathbf{x})\} \tag{1}
\end{equation*}
$$

- $f$ and $g$ are both proper, closed, and convex.
- $\operatorname{dom}(F):=\operatorname{dom}(f) \cap \operatorname{dom}(g) \neq \emptyset$ and $-\infty<F^{\star}<+\infty$.
- The solution set $\mathcal{S}^{\star}:=\left\{\mathbf{x}^{\star} \in \operatorname{dom}(F): F\left(\mathbf{x}^{\star}\right)=F^{\star}\right\}$ is nonempty.

## How can we better adapt to the local geometry?

Non-adaptive:

$\begin{array}{ll}\|\nabla f(x)-\nabla f(y)\| \leq L\|y-x\| & x_{2} \uparrow \\ \mathrm{~L} \text { is a global worst-case constant }\end{array}$

How can we better adapt to the local geometry?
Line-search:

How can we better adapt to the local geometry?
Variable metric:

L is a global worst-case constant

## The idea of the proximal-Newton method

## Assumptions A. 2

Assume that $f \in \mathcal{F}_{L, \mu}^{2,1}\left(\mathbb{R}^{p}\right)$ and $g \in \mathcal{F}_{\text {prox }}\left(\mathbb{R}^{p}\right)$.
Optimality condition of (1):

$$
\begin{equation*}
0 \in \nabla f\left(\mathbf{x}^{\star}\right)+\partial g\left(\mathbf{x}^{\star}\right) . \tag{2}
\end{equation*}
$$

The idea of proximal-Newton method

- Given $\mathbf{x}^{k}$, under Assumptions A.2, we can linearize the smooth term of the (2):

$$
0 \in \nabla f\left(\mathbf{x}^{\star}\right)+\partial g\left(\mathbf{x}^{\star}\right) \approx \nabla f\left(\mathbf{x}^{k}\right)+\nabla^{2} f\left(\mathbf{x}^{k}\right)^{T}\left(\mathbf{x}^{\star}-\mathbf{x}^{k}\right)+\partial g\left(\mathbf{x}^{\star}\right) .
$$

- Similar to the classical Newton method: Solving

$$
\begin{equation*}
0 \in \nabla f\left(\mathbf{x}^{k}\right)+\nabla^{2} f\left(\mathbf{x}^{k}\right)^{T}\left(\mathbf{x}-\mathbf{x}^{k}\right)+\partial g(\mathbf{x}) \tag{3}
\end{equation*}
$$

to obtain $\mathrm{x}^{k+1}$.

- The last condition is equivalent to

$$
\begin{equation*}
\mathbf{x}^{k+1}:=\underset{\mathbf{x} \in \mathbb{R}^{p}}{\arg \min _{2}}\left\{\frac{1}{2}\left(\mathbf{x}-\mathbf{x}^{k}\right)^{T} \nabla^{2} f\left(\mathbf{x}^{k}\right)\left(\mathbf{x}-\mathbf{x}^{k}\right)+\nabla f\left(\mathbf{x}^{k}\right)^{T}\left(\mathbf{x}-\mathbf{x}^{k}\right)+g(\mathbf{x})\right\} . \tag{4}
\end{equation*}
$$

## Proximal-quasi-Newton-type algorithms

- Let $\mathbf{H}_{k} \approx \nabla^{2} f\left(\mathbf{x}^{k}\right)$ be a symmetric positive definite (SDP) matrix. Then, we have

$$
\mathbf{x}^{k}-\mathbf{H}_{k}^{-1} \nabla f\left(\mathbf{x}^{k}\right) \in\left(\mathbb{I}+\mathbf{H}_{k}^{-1} \partial g\right)\left(\mathbf{x}^{k+1}\right)
$$

or

$$
\begin{equation*}
\mathbf{x}^{k+1}:=\operatorname{prox}_{\mathbf{H}_{k}^{-1} g}\left(\mathbf{x}^{k}-\mathbf{H}_{k}^{-1} \nabla f\left(\mathbf{x}^{k}\right)\right) . \tag{5}
\end{equation*}
$$

- By letting $\mathbf{d}^{k}:=\mathbf{x}^{k+1}-\mathbf{x}^{k}$, (5) is equivalent to

$$
\begin{equation*}
\mathbf{d}^{k}:=\arg \min _{\mathbf{d} \in \mathbb{R}^{p}}\left\{\frac{1}{2} \mathbf{d}^{T} \mathbf{H}_{k} \mathbf{d}+\nabla f\left(\mathbf{x}^{k}\right)^{T} \mathbf{d}+g\left(\mathbf{x}^{k}+\mathbf{d}\right)\right\} . \tag{6}
\end{equation*}
$$

Then $\mathbf{d}^{k}$ is called a proximal-Newton-type direction.

- Proximal-Newton-type algorithm generates a sequence $\left\{\mathbf{x}^{k}\right\}_{k \geq 0}$ starting from $\mathbf{x}^{0} \in \mathbb{R}^{p}$ and update:

$$
\begin{equation*}
\mathbf{x}^{k+1}:=\mathbf{x}^{k}+\alpha_{k} \mathbf{d}^{k} \tag{7}
\end{equation*}
$$

where $\mathbf{d}^{k}$ is given by (6) and $\alpha_{k} \in(0,1]$ is a damped step-size.

## How to find step size $\alpha_{k}$ ?

## Lemma (Descent lemma [6])

Let $\mathbf{x}^{k}(\alpha):=\mathbf{x}^{k}+\alpha \mathbf{d}^{k}$ for sufficiently small $\alpha \in(0,1]$ and $\mathbf{H}_{k} \succ 0$. Then, we have:

$$
F\left(\mathbf{x}^{k}(\alpha)\right) \leq F\left(\mathbf{x}^{k}\right)-(1 / 2) \alpha\left(\mathbf{d}^{k}\right)^{T} \mathbf{H}_{k} \mathbf{d}^{k}+\mathcal{O}\left(\alpha^{2}\right) .
$$

Since $\mathbf{H}_{k} \succ 0$, this lemma tells us that:

- If $\mathbf{d}^{k} \neq 0$, then there exists $\alpha>0$ such that $F\left(\mathbf{x}^{k}(\alpha)\right)<F\left(\mathbf{x}^{k}\right)$.
- The value of $\alpha$ can be computed via backtracking line search.
- If $\mathbf{d}^{k}=0$, then we can easily check that $\mathbf{x}^{k}$ is a solution of (1).

## Backtracking line-search

- Let

$$
r_{k}:=\nabla f\left(\mathbf{x}^{k}\right)^{T} \mathbf{d}^{k}+g\left(\mathbf{x}^{k}+\mathbf{d}^{k}\right)-g\left(\mathbf{x}^{k}\right) .
$$

- Find the smallest integer number $j \geq 0$ such that $\alpha_{k}:=\beta^{j}$ and

$$
\begin{equation*}
F\left(\mathbf{x}^{k}+\alpha_{k} \mathbf{d}^{k}\right) \leq F\left(\mathbf{x}^{k}\right)+c \alpha_{k} r_{k}, \tag{8}
\end{equation*}
$$

where $c \in(0,0.5]$ and $\beta \in(0,1)$ are two given constants (e.g., $c=0.1$ and $\beta=0.5$ ).

## The proximal-Newton-type algorithm

We can summary the proximal-Newton-type method as follows:

| Proximal-Newton algorithm (PNA) |
| :--- |
| 1. Given $\mathbf{x}^{0} \in \mathbb{R}^{p}$ as a starting point. Choose $c:=0.1$ and |
| $\beta:=0.5$ |
| 2. For $k=0,1, \cdots$, perform the following steps: |
| 2.1. Evaluate an SDP matrix $\mathbf{H}_{k} \approx \nabla^{2} f\left(\mathbf{x}^{k}\right)$ and $\nabla f\left(\mathbf{x}^{k}\right)$. |
| 2.2. Compute $\mathbf{d}^{k}:=\operatorname{prox}_{\mathbf{H}_{k}^{-1} g}\left(\mathbf{x}^{k}-\mathbf{H}_{k}^{-1} \nabla f\left(\mathbf{x}^{k}\right)\right)-\mathbf{x}^{k}$. |
| 2.3. Find the smallest integer number $j \geq 0$ such that |
| $\qquad F\left(\mathbf{x}^{k}+\beta^{j} \mathbf{d}^{k}\right) \leq F\left(\mathbf{x}^{k}\right)+c \beta^{j} r_{k}$ |
| and set $\alpha_{k}:=\beta^{j}$. |
| 2.4. Update $\mathbf{x}^{k+1}:=\mathbf{x}^{k}+\alpha_{k} \mathbf{d}^{k}$. |

- If $\mathbf{H}_{k} \equiv \nabla^{2} f\left(\mathbf{x}^{k}\right)$, then PNA becomes a pure proximal-Newton algorithm.
- If $\mathbf{H}_{k} \approx \nabla^{2} f\left(\mathbf{x}^{k}\right)$, then PNA becomes a proximal-quasi-Newton algorithm.
- Main computation is Step 2.2, which requires a generalized prox-operator: $\operatorname{prox}_{\mathbf{H}_{k}^{-1} g}\left(\mathbf{x}^{k}+\mathbf{H}_{k}^{-1} \nabla f\left(\mathbf{x}^{k}\right)\right)$.
- Let $g(\mathbf{x})=\rho\|\mathbf{x}\|_{1}$. When $\mathbf{H}_{k}$ is not diagonal, the cost is the same as solving an $\ell_{1}$-regularized least squares, otherwise it is simply soft thresholding.

## Convergence analysis

## Assumption A.3.

- The subproblem $\operatorname{prox}_{\mathbf{H}_{k}^{-1} g}\left(\mathbf{x}^{k}+\mathbf{H}_{k}^{-1} \nabla f\left(\mathbf{x}^{k}\right)\right)$ is solved exactly for all $k \geq 0$.

## Theorem (Global convergence [6])

## Assumptions:

- The sequence $\left\{\mathrm{x}^{k}\right\}_{k \geq 0}$ is generated by PNA.
- Assumption A.3. is satisfied.
- There exists $\mu>0$ such that $\mathbf{H}_{k} \succeq \mu \mathbb{I}$ for all $k \geq 0$.

## Conclusion:

- $\left\{\mathbf{x}^{k}\right\}_{k \geq 0}$ globally converges to a solution $\mathbf{x}^{\star}$ of (1).
- We have not yet obtained a global convergence rate of proximal-Newton methods.

## Convergence analysis

## Assumption A. 3 .

- The subproblem $\operatorname{prox}_{\mathbf{H}_{k}^{-1} g}\left(\mathbf{x}^{k}+\mathbf{H}_{k}^{-1} \nabla f\left(\mathbf{x}^{k}\right)\right)$ is solved exactly for all $k \geq 0$.

## Theorem (Local convergence [6])

## Assumptions:

- The sequence $\left\{\mathbf{x}^{k}\right\}_{k \geq 0}$ is generated by PNA.
- Assumption A.3. is satisfied.
- Exist $0<\mu \leq L_{2}<+\infty$ such that $\mu \mathbb{I} \preceq \mathbf{H}_{k} \preceq L_{2} \mathbb{I}$ for all sufficiently large $k$.

## Conclusion:

- If $\mathbf{H}_{k} \equiv \nabla^{2} f\left(\mathbf{x}^{k}\right)$, then $\alpha_{k}=1$ for $k$ sufficiently large (full-step).
- If $\mathbf{H}_{k} \equiv \nabla^{2} f\left(\mathbf{x}^{k}\right)$, then $\left\{\mathbf{x}^{k}\right\}$ locally converges to $\mathbf{x}^{\star}$ at a quadratic rate.
- If $\mathbf{H}_{k}$ satisfies the Dennis-Moré condition:

$$
\begin{equation*}
\lim _{k \rightarrow+\infty} \frac{\left\|\left(\mathbf{H}_{k}-\nabla^{2} f\left(\mathbf{x}^{\star}\right)\right)\left(\mathbf{x}^{k+1}-\mathbf{x}^{k}\right)\right\|}{\left\|\mathbf{x}^{k+1}-\mathbf{x}^{k}\right\|}=0 \tag{9}
\end{equation*}
$$

then $\left\{\mathbf{x}^{k}\right\}$ locally converges to $\mathbf{x}^{\star}$ at a super linear rate.

## How to compute the approximation $\mathrm{H}_{k}$ ?

## How to update $\mathbf{H}_{k}$ ?

Matrix $\mathbf{H}_{k}$ can be updated by using low-rank updates.

- BFGS update: maintain the Dennis-Moré condition and $\mathbf{H}_{k} \succ 0$.

$$
\mathbf{H}_{k+1}:=\mathbf{H}_{k}+\frac{\mathbf{y}_{k} \mathbf{y}_{k}^{T}}{\mathbf{s}_{k}^{T} \mathbf{y}_{k}}-\frac{\mathbf{H}_{k} \mathbf{s}_{k} \mathbf{s}_{k}^{T} \mathbf{H}_{k}}{\mathbf{s}_{k}^{T} \mathbf{H}_{k} \mathbf{s}_{k}}, \quad \mathbf{H}_{0}:=\gamma \mathbb{I}, \quad(\gamma>0) .
$$

where $\mathbf{y}_{k}:=\nabla f\left(\mathbf{x}^{k+1}\right)-\nabla f\left(\mathbf{x}^{k}\right)$ and $\mathbf{s}_{k}:=\mathbf{x}^{k+1}-\mathbf{x}^{k}$.

- Diagonal+Rank-1 [2]: computing PN direction $\mathbf{d}^{k}$ is in polynomial time, but it does not maintain the Dennis-Moré condition:

$$
\mathbf{H}_{k}:=\mathbf{D}_{k}+\mathbf{u}_{k} \mathbf{u}_{k}^{T}, \quad \mathbf{u}_{k}:=\left(\mathbf{s}_{k}-\mathbf{H}_{0} \mathbf{y}_{k}\right) / \sqrt{\left(\mathbf{s}_{k}-\mathbf{H}_{0} \mathbf{y}_{k}\right)^{T} \mathbf{y}_{k}},
$$

where $\mathbf{D}_{k}$ is a positive diagonal matrix.

## Advantages and disadvantages

## Advantages

- PNA has fast local convergence rate (super-linear or quadratic)
- Numerical robustness under the inexactness/noise (inexact proximal-Newton method [6]).
- Quasi-Newton method is useful if the evaluation of $\nabla^{2} f$ is expensive.
- Suitable for problems with many data points but few parameters. For example, problems of the form:

$$
F^{*}:=\min _{\mathbf{x} \in \mathbb{R}^{p}}\left\{\sum_{j=1}^{n} \ell_{j}\left(\mathbf{a}_{j}^{T} \mathbf{x}+b_{j}\right)+g(\mathbf{x})\right\}
$$

where $\ell_{j}$ is twice continuously differentiable and convex, $g \in \mathcal{F}_{\text {prox }}, p \ll n$.

## Disadvantages

- Expensive iteration compared to proximal-gradient methods.
- Global convergence rate may be worse than accelerated proximal-gradient methods.
- Requires a good initial point to get fast local convergence, which is hard to find.
- Requires strict conditions for global/local convergence analysis.

## Example 1: Sparse logistic regression

## Problem (Sparse logistic regression)

Given a sample vector $\mathbf{a} \in \mathbb{R}^{p}$ and a binary class label vector $\mathbf{b} \in\{-1,+1\}^{n}$. The conditional probability of a label $b$ given $\mathbf{a}$ is defined as:

$$
\mathbb{P}(b \mid \mathbf{a}, \mathbf{x}, \mu)=1 /\left(1+e^{-b\left(\mathbf{x}^{T} \mathbf{a}+\mu\right)}\right)
$$

where $\mathbf{x} \in \mathbb{R}^{p}$ is a weight vector, $\mu$ is called the intercept.
Goal: Find a sparse-weight vector $\mathbf{x}$ via the maximum likelihood principle.

## Optimization formulation

$$
\begin{equation*}
\min _{\mathbf{x} \in \mathbb{R}^{p}}\{\underbrace{\frac{1}{n} \sum_{i=1}^{n} \mathcal{L}\left(b_{i}\left(\mathbf{a}_{i}^{T} \mathbf{x}+\mu\right)\right.}_{f(\mathbf{x})})+\underbrace{\rho\|\mathbf{x}\|_{1}}_{g(\mathbf{x})}\} \tag{10}
\end{equation*}
$$

where $\mathbf{a}_{i}$ is the $i$-th row of data matrix $\mathbf{A}$ in $\mathbb{R}^{n \times p}, \rho>0$ is a regularization parameter, and $\ell$ is the logistic loss function $\mathcal{L}(\tau):=\log \left(1+e^{-\tau}\right)$.

## Example: Sparse logistic regression

## Real data

- Real data: w2a with $n=3470$ data points, $p=300$ features
- Available at http://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/binary.html.

## Parameters

- Tolerance $10^{-6}$.
- L-BFGS memory $m=50$.
- Ground truth: Get a high accuracy approximation of $\mathbf{x}^{\star}$ and $f^{\star}$ by TFOCS with tolerance $10^{-12}$.

## Example: Sparse logistic regression-Numerical results

## Example 2: $\ell_{1}$-regularized least squares

## Problem ( $\ell_{1}$-regularized least squares)

Given $\mathbf{A} \in \mathbb{R}^{n \times p}$ and $\mathbf{b} \in \mathbb{R}^{n}$, solve:

$$
\begin{equation*}
F^{\star}:=\min _{\mathbf{x} \in \mathbb{R}^{p}}\left\{F(\mathbf{x}):=\frac{1}{2}\|\mathbf{A} \mathbf{x}-\mathbf{b}\|_{2}^{2}+\rho\|\mathbf{x}\|_{1}\right\} \tag{11}
\end{equation*}
$$

where $\rho>0$ is a regularization parameter.

## Complexity per iterations

- Evaluating $\nabla f\left(\mathbf{x}^{k}\right)=\mathbf{A}^{T}\left(\mathbf{A} \mathbf{x}^{k}-\mathbf{b}\right)$ requires one $\mathbf{A x}$ and one $\mathbf{A}^{T} \mathbf{y}$.
- One soft-thresholding operator $\operatorname{prox}_{\lambda g}(\mathbf{x})=\operatorname{sign}(\mathbf{x}) \otimes \max \{|\mathbf{x}|-\rho, 0\}$.
- Optional: Evaluating $L=\left\|\mathbf{A}^{T} \mathbf{A}\right\|$ (spectral norm) - via power iterations (e.g., 20 iterations, each iteration requires one $\mathbf{A x}$ and one $\mathbf{A}^{T} \mathbf{y}$ ).

## Synthetic data generation

- A $:=\operatorname{randn}(n, p)$ - standard Gaussian $\mathcal{N}(0, \mathbb{I})$.
- $\mathbf{x}^{\star}$ is a $s$-sparse vector generated randomly.
- $\mathbf{b}:=\mathbf{A} \mathbf{x}^{\star}+\mathcal{N}\left(0,10^{-3}\right)$.

## Example 2: $\ell_{1}$-regularized least squares - Numerical results - Trial 1

Parameters: $n=750, p=2000, s=200, \rho=1$

## Example 2: $\ell_{1}$-regularized least squares - Numerical results - Trial 2

Parameters: $n=750, p=2000, s=200, \rho=1$

## Outline

- Today

1. Proximal Newton-type method.
2. Stochastic proximal gradient method.
3. Stochastic proximal gradient method with progressive variance reduction.

- Next week

1. Constrained convex minimization I: The primal-dual approach.
2. Smoothing approaches for non-smooth convex minimization.

## Convex composite minimization

## Problem (Mathematical formulation)

Consider the following constrained convex minimization problem:

$$
F^{\star}=\min _{\mathbf{x} \in \mathbb{R}^{p}}\{F(\mathbf{x}):=\mathbb{E}[h(\mathbf{x}, \theta)]+g(\mathbf{x})\}
$$

- $\theta$ is a random vector whose probability distribution is supported on set $\Theta$.
- The solution set $\mathcal{S}^{\star}:=\left\{\mathbf{x}^{\star} \in \operatorname{dom}(F): F\left(\mathbf{x}^{\star}\right)=F^{\star}\right\}$ is nonempty.
- $h(\mathbf{x}, \theta) \in \mathcal{F}_{L_{\theta}}^{1,1}\left(\mathbb{R}^{p}\right)$ and $f=\mathbb{E}[h(\mathbf{x}, \theta)] \in \mathcal{F}_{L}^{1,1}\left(\mathbb{R}^{p}\right)$.
- $g \in \mathcal{F}_{\mathrm{prox}}\left(\mathbb{R}^{p}\right)$.
- When $g=0$, the problem reduces to the one considered in Lecture 7. Every example in Lecture 7 can be extended accordingly to the above formulation.
- The goal of this lecture is to extend the methods in Lecture 7 for a non-zero $g$.

## Stochastic proximal gradient method

## Stochastic proximal gradient method (SPG)

1. Choose $\mathbf{x}^{0} \in \mathbb{R}^{p}$ and $\left.\left(\gamma_{k}\right)_{k \in \mathbb{N}} \in\right] 0,+\infty\left[^{\mathbb{N}}\right.$.
2. For $k=0,1, \ldots$ perform:

$$
\mathbf{x}^{k+1}=\operatorname{prox}_{\gamma_{k} g}\left(\mathbf{x}^{k}-\gamma_{k} G\left(\mathbf{x}^{k}, \theta_{k}\right)\right)
$$

- We assume that $\left\{\theta_{k}\right\}$ are jointly independent and $G\left(\mathbf{x}^{k}, \theta_{k}\right)$ is an unbiased estimate of the full gradient, i.e., it satisfies

$$
\mathbb{E}\left[G\left(\mathbf{x}^{k}, \theta_{k}\right)\right]=\nabla f\left(\mathbf{x}^{k}\right)
$$

- We obtain the SG method in Lecture 7 when $g=0$.

## Stochastic proximal gradient method

## Stochastic proximal gradient method (SPG)

1. Choose $\mathbf{x}^{0} \in \mathbb{R}^{p}$ and $\left.\left(\gamma_{k}\right)_{k \in \mathbb{N}} \in\right] 0,+\infty \mathbb{N}^{\mathbb{N}}$.
2. For $k=0,1, \ldots$ perform:

$$
\mathbf{x}^{k+1}=\operatorname{prox}_{\gamma_{k} g}\left(\mathbf{x}^{k}-\gamma_{k} G\left(\mathbf{x}^{k}, \theta_{k}\right)\right)
$$

- We assume that $\left\{\theta_{k}\right\}$ are jointly independent and $G\left(\mathbf{x}^{k}, \theta_{k}\right)$ is an unbiased estimate of the full gradient, i.e., it satisfies

$$
\mathbb{E}\left[G\left(\mathbf{x}^{k}, \theta_{k}\right)\right]=\nabla f\left(\mathbf{x}^{k}\right)
$$

- We obtain the SG method in Lecture 7 when $g=0$.

## Remark

- SPG shares the same structure as the proximal gradient method, but the gradient is replaced by an unbiased estimate in the 2nd step. The cost of computing this estimate is typically much cheaper than that of $\nabla f\left(\mathbf{x}^{k}\right)$.
- As $G\left(\mathbf{x}^{k}, \theta_{k}\right)$ is an unbiased estimate of the full gradient, we expect that SPG would also perform well.

## Convergence analysis

## Assumption A4.

(i) The variance is bounded: $\mathbb{E}_{\theta}\left[\|G(\mathbf{x}, \theta)-\nabla f(x)\|^{2}\right] \leq \sigma^{2}$
(ii) The step size $\left(\gamma_{k}\right)_{k \in \mathbb{N}} \in \ell^{2}(\mathbb{N}) \backslash \ell^{1}(\mathbb{N})$, i.e.,

$$
\sum_{k=0}^{\infty} \gamma_{k}=\infty \text { and } \sum_{k=0}^{\infty} \gamma_{k}^{2}<+\infty
$$

## Theorem (Ergodic convergence)

## Assumptions:

- The sequence $\left\{\mathbf{x}^{k}\right\}_{k \geq 0}$ is generated by SPG.
- Assumption A4. is satisfied and the set of solutions is non-empty.

## Conclusion:

- Define $\hat{\mathbf{x}}^{s}=\left(\sum_{k=0}^{s} \gamma_{k} \mathbf{x}^{k}\right) / \sum_{k=0}^{s} \gamma_{k}$, then

$$
\mathbb{E} F\left(\hat{\mathbf{x}}^{s}\right)-F\left(\mathbf{x}^{\star}\right) \leq\left(0.5\left\|\mathbf{x}^{0}-\mathbf{x}^{\star}\right\|^{2}+\sigma^{2} \sum_{k=0}^{\infty} \gamma_{k}^{2}\right) / \sum_{k=0}^{s} \gamma_{k}
$$

## Convergence analysis

## Assumption A4.

(i) The variance is bounded: $\mathbb{E}_{\theta}\left[\|G(\mathbf{x}, \theta)-\nabla f(x)\|^{2}\right] \leq \sigma^{2}$
(ii) The step size $\left(\gamma_{k}\right)_{k \in \mathbb{N}} \in \ell^{2}(\mathbb{N}) \backslash \ell^{1}(\mathbb{N})$, i.e.,

$$
\sum_{k=0}^{\infty} \gamma_{k}=\infty \text { and } \sum_{k=0}^{\infty} \gamma_{k}^{2}<+\infty
$$

## Theorem (Non-ergodic convergence [14])

## Assumptions:

- The sequence $\left\{\mathbf{x}^{k}\right\}_{k \geq 0}$ is generated by SPG.
- Assumption A4(i). is satisfied and $\gamma_{k} \sim 1 /(k+1)$.
- $f$ is $\mu$-strongly convex.

## Conclusion:

- $1 / k$ rate is obtained:

$$
\mathbb{E}\left\|\mathbf{x}^{k}-\mathbf{x}^{\star}\right\|^{2}=\mathcal{O}(1 / k)
$$

- If $F$ is $R$-smooth, i.e. $F(\mathbf{x})-F\left(\mathbf{x}^{\star}\right) \leq R\left\|\mathbf{x}-\mathbf{x}^{\star}\right\|^{2}$, then

$$
\mathbb{E} F\left(\mathbf{x}^{k}\right)-F\left(\mathbf{x}^{\star}\right)=\mathcal{O}(1 / k) .
$$

## Composite optimization with finite sums

## Composite optimization with finite sums

$$
\begin{equation*}
F^{\star}:=\min _{\mathbf{x} \in \operatorname{dom}(F)}\left\{F(\mathbf{x}):=\frac{1}{m} \sum_{k=1}^{m} f_{k}(\mathbf{x})+g(\mathbf{x})\right\} \tag{12}
\end{equation*}
$$

- $f_{k} \in \mathcal{F}_{L_{k}}^{1,1}\left(\mathbb{R}^{p}\right)$ and $f=\frac{1}{k} \sum_{k=1}^{m} f_{k} \in \mathcal{F}_{L}^{1,1}\left(\mathbb{R}^{p}\right)$.
- $g \in \mathcal{F}_{\text {prox }}\left(\mathbb{R}^{p}\right)$.

Why is stochastic minimization?

- $f(\mathbf{x})=\mathbb{E}_{j} f_{j}(\mathbf{x})$ where $\mathbb{P}(j=k)=1 / m$.
- Computation $\nabla f(x)=\frac{1}{m} \sum_{k=1}^{m} \nabla f_{k}(\mathbf{x})$ is expensive when $m \gg 1$.
- Covers many well-known examples in maching learning, portfolio optimization, SVM.

## Large scale problems

## Definition (Recall)

- $\nabla f_{j}$ is called the stochastic gradient of $f$, and it is unbiased estimate, i.e.

$$
\mathbb{E}_{j} \nabla f_{j}(\mathbf{x})=\sum_{i=1}^{m} \mathbb{P}(j=k) \nabla f_{k}(\mathbf{x})=\frac{1}{m} \sum_{i=1}^{m} \nabla f_{k}(\mathbf{x})=\nabla f(\mathbf{x})
$$

- $\mathbb{E}_{j}\left\|\nabla f_{j}(\mathbf{x})-\nabla f(\mathbf{x})\right\|^{2}$ is called variance.

## Example

Define $f(\mathbf{x})=\frac{1}{2 m}\|\mathbf{A} \mathbf{x}-\mathbf{b}\|^{2}$ with $\mathbf{b} \in \mathbb{R}^{m}$. To find stochastic gradient, observe:

$$
f(\mathbf{x})=\frac{1}{2 m} \sum_{k=1}^{m}\left|\mathbf{a}_{k}^{T} \mathbf{x}-\mathbf{b}_{k}\right|^{2}
$$

Thus,

$$
f_{j}(\mathbf{x})=\frac{1}{2}\left|\mathbf{a}_{j}^{T} \mathbf{x}-\mathbf{b}_{j}\right|^{2} \text { with } \nabla f_{j}(\mathbf{x})=\left(\mathbf{a}_{j}^{T} \mathbf{x}-\mathbf{b}_{j}\right) \mathbf{a}_{j}
$$

## Large scale problems

## Definition (Recall)

- $\nabla f_{j}$ is called the stochastic gradient of $f$, and it is unbiased estimate, i.e.

$$
\mathbb{E}_{j} \nabla f_{j}(\mathbf{x})=\sum_{i=1}^{m} \mathbb{P}(j=k) \nabla f_{k}(\mathbf{x})=\frac{1}{m} \sum_{i=1}^{m} \nabla f_{k}(\mathbf{x})=\nabla f(\mathbf{x})
$$

- $\mathbb{E}_{j}\left\|\nabla f_{j}(\mathbf{x})-\nabla f(\mathbf{x})\right\|^{2}$ is called variance.

## Example

Similarly, one can find stochastic gradient of

1. $f(\mathbf{x})=\frac{1}{m} \sum_{i=1}^{m} \log \left(1+\exp \left(-\mathbf{b}_{i} \mathbf{a}_{i}^{T} \mathbf{x}\right)\right)$ where $\mathbf{a}_{i} \in \mathbb{R}^{p}, \mathbf{b}_{i}= \pm 1$.
2. $f(\mathbf{x})=\frac{1}{2} \mathbf{x}^{T} \mathbf{Q} \mathbf{x}$ where $\mathbf{Q}$ is positive semidefinite matrix.
3. $f(\mathbf{x})=\frac{1}{m} \sum_{i=1}^{m}\left(\mathbf{a}_{i}^{T} \mathbf{x}-\overline{\mathbf{b}}\right)^{2}$ where $\mathbf{a}_{i} \in \mathbb{R}^{p}, \overline{\mathbf{b}} \in \mathbb{R}$.

## Stochastic proximal gradient algorithm for the finite sum problem

## Stochastic proximal gradient algorithm (SPG) [4, 14]

1. Choose $\mathbf{x}^{0} \in \mathbb{R}^{p}$ as a starting point and $\gamma_{0}>0$.
2. For $k=0,1, \cdots$, perform:

$$
\left\{\begin{array}{l}
\text { Pick } i_{k} \in\{1, \ldots, m\} \text { uniformly at random }  \tag{13}\\
\mathbf{x}^{k+1}:=\operatorname{prox}_{\gamma_{k} g}\left(\mathbf{x}^{k}-\gamma_{k} \nabla f_{i_{k}}\left(\mathbf{x}^{k}\right)\right)
\end{array}\right.
$$

where $\gamma_{k} \in(0,1 / L]$ is a given step size aka learning rate

## Common features

- SPG shares the same structure as PG (proximal gradient) where the full gradient is replaced by stochastic gradient. Thus, SPG only evaluates gradient of a single component function.
- The computational cost per iteration is only $1 / m$ that of the PG method.
- $L \leq m^{-1} \sum_{k=1}^{m} L_{k} \leq L_{\max }=\max _{1 \leq k \leq m} L_{k}$.
- To ensure convergnce, the step size is often chosen such that $\left(\gamma_{k}\right)_{k \in \mathbb{N}} \in \ell^{2}(\mathbb{N}) \backslash \ell^{1}(\mathbb{N})$.

## Stochastic proximal gradient algorithm for the finite sum problem

Stochastic proximal gradient algorithm (SPG) [4, 14]

1. Choose $\mathbf{x}^{0} \in \mathbb{R}^{p}$ as a starting point and $\gamma_{0}>0$.
2. For $k=0,1, \cdots$, perform:

$$
\left\{\begin{array}{l}
\text { Pick } i_{k} \in\{1, \ldots, m\} \text { uniformly at random }  \tag{14}\\
\mathbf{x}^{k+1}:=\operatorname{prox}_{\gamma_{k} g}\left(\mathbf{x}^{k}-\gamma_{k} \nabla f_{i_{k}}\left(\mathbf{x}^{k}\right)\right)
\end{array}\right.
$$

where $\gamma_{k} \in(0,1 / L]$ is a given step size aka learning rate

## Complexity per iteration: One gradient and prox

- Evaluation of $\nabla f_{i_{k}}\left(\mathbf{x}^{k}\right)$ is much cheaper than $\nabla f\left(\mathbf{x}^{k}\right)$.
- Closed-form expressions for prox $\gamma_{k} g$ are given in previous lecture for several $g$.

## Convergence analysis

## Assumption A4.

(i) The variance is bounded: $\mathbb{E}_{j}\left[\left\|\nabla f_{j}(x)-\nabla f(x)\right\|^{2}\right] \leq \sigma^{2}$
(ii) The step size $\left(\gamma_{k}\right)_{k \in \mathbb{N}} \in \ell^{2}(\mathbb{N}) \backslash \ell^{1}(\mathbb{N})$, i.e.,

$$
\sum_{k=0}^{\infty} \gamma_{k}=\infty \text { and } \sum_{k=0}^{\infty} \gamma_{k}^{2}<+\infty
$$

## Theorem (Ergodic convergence)

## Assumptions:

- The sequence $\left\{\mathbf{x}^{k}\right\}_{k \geq 0}$ is generated by SPG.
- Assumption A4. is satisfied and the set of solutions is non-empty.

## Conclusion:

- Define $\hat{\mathbf{x}}^{s}=\left(\sum_{k=0}^{s} \gamma_{k} \mathbf{x}^{k}\right) / \sum_{k=0}^{s} \gamma_{k}$, then

$$
\mathbb{E} F\left(\hat{\mathbf{x}}^{s}\right)-F\left(\mathbf{x}^{\star}\right) \leq\left(0.5\left\|\mathbf{x}^{0}-\mathbf{x}^{\star}\right\|^{2}+\sigma^{2} \sum_{k=0}^{\infty} \gamma_{k}^{2}\right) / \sum_{k=0}^{s} \gamma_{k}
$$

## Convergence analysis

## Assumption A4.

(i) The variance is bounded: $\mathbb{E}_{j}\left[\left\|\nabla f_{j}(x)-\nabla f(x)\right\|^{2}\right] \leq \sigma^{2}$
(ii) The step size $\left(\gamma_{k}\right)_{k \in \mathbb{N}} \in \ell^{2}(\mathbb{N}) \backslash \ell^{1}(\mathbb{N})$, i.e.,

$$
\sum_{k=0}^{\infty} \gamma_{k}=\infty \text { and } \sum_{k=0}^{\infty} \gamma_{k}^{2}<+\infty
$$

## Theorem (Non-ergodic convergence [14])

## Assumptions:

- The sequence $\left\{\mathbf{x}^{k}\right\}_{k \geq 0}$ is generated by SPG.
- Assumption A4(i). is satisfied and $\gamma_{k} \sim 1 /(k+1)$.
- $f$ is $\mu$-strongly convex.

## Conclusion:

- $1 / k$ rate is obtained:

$$
\mathbb{E}\left\|\mathbf{x}^{k}-\mathbf{x}^{\star}\right\|^{2}=\mathcal{O}(1 / k)
$$

- If $F$ is $R$-smooth, i.e. $F(\mathbf{x})-F\left(\mathbf{x}^{\star}\right) \leq R\left\|\mathbf{x}-\mathbf{x}^{\star}\right\|^{2}$, then

$$
\mathbb{E} F\left(\mathbf{x}^{k}\right)-F\left(\mathbf{x}^{\star}\right)=\mathcal{O}(1 / k) .
$$

## Comparisons

- SPG vs PG

| Algorithm | $\gamma_{k} \rightarrow 0$ | Strong <br> convexity | Convergence | Rate | $\#$ <br> grad/Iter. |
| :--- | :--- | :--- | :--- | :--- | :--- |
| PG | No | No | Ergodic | $1 / \mathrm{k}$ | $m$ |
| SPG | Yes | No | Ergodic | $1 / \sum_{j=0}^{k-1} \gamma_{j}$ | 1 |
| PG | No | Yes | Non-Ergodic | Linear | $m$ |
| SPG | Yes | Yes | Non-Ergodic | $1 / k$ | 1 |

- PG= Proximal gradient, aka Forward-backward.
- $\mathrm{SPG}=$ Stochastic Proximal gradient.

## Comparisons

- SPG vs PG

| Algorithm | $\gamma_{k} \rightarrow 0$ | Strong <br> convexity | Convergence | Rate | $\#$ <br> grad/Iter. |
| :--- | :--- | :--- | :--- | :--- | :--- |
| PG | No | No | Ergodic | $1 / \mathrm{k}$ | $m$ |
| SPG | Yes | No | Ergodic | $1 / \sum_{j=0}^{k-1} \gamma_{j}$ | 1 |
| PG | No | Yes | Non-Ergodic | Linear | $m$ |
| SPG | Yes | Yes | Non-Ergodic | $1 / k$ | 1 |

- PG= Proximal gradient, aka Forward-backward.
- $\mathrm{SPG}=$ Stochastic Proximal gradient.
- Advantages and disadvantages of SPG
- Complexity per iteration is very low and hence SPG is suitable for large problems such as SVM, logistic regression.
- The convergence rate is slower than PG and hence SPG is suitable when we require only low accurate of solution.

Conclusion: SPG $\rightarrow$ Large scale problems + low accurate of solution

- The bounded variance condition is standard but it is hard to evaluate and hence the learning rate need to go to 0 to cancel its growth.

> Soltuion: Use the variance reduction technique (see Prox-SVRG)

## Example: $\ell_{1}$-regularized least squares revisited

## Problem ( $\ell_{1}$-regularized least squares)

Given $\mathbf{A} \in \mathbb{R}^{m \times p}$ and $\mathbf{b} \in \mathbb{R}^{m}$, solve:

$$
\begin{equation*}
F^{\star}:=\min _{\mathbf{x} \in \mathbb{R}^{p}}\left\{F(\mathbf{x}):=\frac{1}{2 m}\|\mathbf{A} \mathbf{x}-\mathbf{b}\|_{2}^{2}+\rho\|\mathbf{x}\|_{1}\right\} \tag{15}
\end{equation*}
$$

where $\rho>0$ is a regularization parameter.

## Complexity per iterations

- Evaluating $\nabla f_{j}\left(\mathbf{x}^{k}\right)=\left(a_{j}^{T} \mathbf{x}^{k}-\mathbf{b}\right) a_{j}$ requires one $a_{j}^{T} \mathbf{x}$ and one $\lambda a_{j}$.
- One soft-thresholding operator $\operatorname{prox}_{\lambda g}(\mathbf{x})=\operatorname{sign}(\mathbf{x}) \otimes \max \{|\mathbf{x}|-\kappa, 0\}$.
- Optional: Evaluating $L_{\text {max }}=\max _{1 \leq k \leq m}\left\|a_{k}\right\|^{2}$ - via iterations.

## Synthetic data generation

- A $:=\operatorname{randn}(m, p)$ - standard Gaussian $\mathcal{N}(0, \mathbb{I})$.
- $\mathbf{x}^{\star}$ is a sparse vector generated randomly.
- $\mathbf{b}:=\mathbf{A} \mathbf{x}^{\star}+\mathcal{N}\left(0,10^{-3}\right)$.

## Example: $\ell_{1}$-regularized least squares revisited- Numerical test

## *Accelerated SPG I

## Accelerated SPG (AccSPG)

0 . $0 \leq \mu$-strong convexity of $F$.

1. Choose $\left.\mathbf{y}^{0}=\mathbf{z}^{0}=\mathbf{0},\left(\gamma_{k}\right)_{k \in \mathbb{N}},\left(\alpha_{k}\right)_{k \in \mathbb{N}} \in\right] 0,+\infty\left[^{\mathbb{N}}, \alpha_{0}=1, \gamma_{0}=L+\mu\right.$.
2. For $k=0,1, \ldots$ perform:

2a. $\mathbf{x}^{k+1}=\left(1-\alpha_{k}\right) \mathbf{y}^{k}+\alpha_{k} \mathbf{z}^{k}$.
2b. $\mathbf{y}^{k+1}=\operatorname{prox}_{g / \gamma_{k}}\left(\mathbf{x}^{k+1}-\frac{1}{\gamma_{k}} G\left(\mathbf{x}^{k+1}, \theta_{k}\right)\right)$.
2c. $\mathbf{z}^{k+1}=\mathbf{z}^{k}-\frac{1}{\gamma_{k} \alpha_{k}+\mu}\left(\gamma_{k}\left(\mathbf{x}^{k+1}-\mathbf{y}^{k+1}\right)+\mu\left(\mathbf{z}^{k}-\mathbf{x}^{k+1}\right)\right)$.

## *Accelerated SPG I

Theorem (Convergence of AccSPG with strong convexity [15])
Define $\lambda_{k}=\prod_{j=1}^{k}\left(1-\alpha_{j}\right)$ and $\lambda_{0}=1$. Le:t

1. $f$ is $\mu$-strongly convex,
2. $\mathbb{E}\left[\left\|\mathbf{z}^{k}-\mathbf{x}^{\star}\right\|^{2}\right] \leq D^{2}$,
3. $\mathbb{E}\left[\left\|G\left(\mathbf{x}^{k}, \theta_{k}\right)-\nabla f\left(\mathbf{x}^{k}\right)\right\|^{2}\right] \leq M^{2}$.
4. $\gamma_{k}=L+\frac{\mu}{\lambda_{k-1}}$ and $\alpha_{k}=\sqrt{\lambda_{k-1}+\frac{\lambda_{k-1}^{2}}{4}}-\frac{\lambda_{k-1}}{2}$.

Then,

$$
\mathbb{E}\left[f\left(\mathbf{y}^{k+1}\right)-f\left(\mathbf{x}^{\star}\right)\right] \leq \frac{2(L+\mu) D^{2}}{k^{2}}+\frac{6 M^{2}}{\mu k}
$$

The accelerated technique can be used to reduce the error term related to $\mathbb{E}\left[\left\|\mathbf{z}^{k}-\mathbf{x}^{\star}\right\|^{2}\right]$.

## *Accelerated SPG II

## Accelerated SPG (AccSPG)

1. Choose $\left.\mathbf{y}^{0}=\mathbf{z}^{0}=\mathbf{0},\left(\gamma_{k}\right)_{k \in \mathbb{N}},\left(\alpha_{k}\right)_{k \in \mathbb{N}} \in\right] 0,+\infty\left[^{\mathbb{N}}, \alpha_{0}=1, \gamma_{0}=L\right.$.
2. For $k=0,1, \ldots$ perform:

2a. $\mathbf{x}^{k+1}=\left(1-\alpha_{k}\right) \mathbf{y}^{k}+\alpha_{k} \mathbf{z}^{k}$.
2b. $\mathbf{y}^{k+1}=\operatorname{prox}_{g / \gamma_{k}}\left(\mathbf{x}^{k+1}-\frac{1}{\gamma_{k}} G\left(\mathbf{x}^{k+1}, \theta_{k}\right)\right)$.
2c. $\mathbf{z}^{k+1}=\mathbf{z}^{k}-\frac{1}{\alpha_{k}}\left(\mathbf{x}^{k+1}-\mathbf{y}^{k+1}\right)$.

## Theorem (Convergence of AccSPG without strong convexity [15])

Let:

1. $\mathbb{E}\left[\left\|\mathbf{z}^{k}-\mathbf{x}^{\star}\right\|^{2}\right] \leq D^{2}$,
2. $\mathbb{E}\left[\left\|G\left(\mathbf{x}^{k}, \theta_{k}\right)-\nabla f\left(\mathbf{x}^{k}\right)\right\|^{2}\right] \leq M^{2}$,
3. $\gamma_{k}=c(k+1)^{3 / 2}+L$ for a fixed $c>0$, and $\alpha_{k}=2 /(k+2)$.

Then,

$$
\mathbb{E}\left[f\left(\mathbf{y}^{k+1}\right)-f\left(\mathbf{x}^{\star}\right)\right] \leq \frac{3 D^{2} L}{k^{2}}+\left(3 D^{2} c+\frac{5 M^{2}}{3 c}\right) \frac{1}{\sqrt{k}} .
$$

## Stochastic proximal gradient algorithm with variance reduction (Prox-SVRG) [13]

## Variance reduction

## Lemma

Given $\widetilde{\mathbf{x}} \in \mathbb{R}^{p}$ and $\mathbb{P}(j=k)=1 / m$, define

$$
\mathbf{r}^{k}=\nabla f_{j}\left(\mathbf{x}^{k}\right)-\nabla f_{j}(\widetilde{\mathbf{x}})+\nabla f(\widetilde{\mathbf{x}}) .
$$

Then, conditioned on $\mathbf{x}^{k}$, we have $\mathbb{E}_{j} \mathbf{r}^{k}=\nabla f\left(\mathbf{x}^{k}\right)$ and

$$
\mathbb{E}_{j}\left\|\mathbf{r}^{k}-\nabla f\left(\mathbf{x}^{k}\right)\right\|^{2} \leq 4 L_{\max }\left(F\left(\mathbf{x}^{k}\right)-F\left(\mathbf{x}^{\star}\right)+F(\widetilde{\mathbf{x}})-F\left(\mathbf{x}^{\star}\right)\right) .
$$

Main idea of Prox-SVRG

- Step 1: Maintain an estimate $\widetilde{\mathbf{x}}$ of $\mathbf{x}^{\star}$ by updating $\widetilde{\mathbf{x}}$ periodically (after $n$-iteration of SPG).
- Step 2: When $\widetilde{\mathbf{x}}$ is updated, we also compute the full gradient:

$$
\nabla f(\widetilde{\mathbf{x}})=\frac{1}{n} \sum_{k=1}^{n} \nabla f_{k}(\widetilde{\mathbf{x}})
$$

- Step 3: Repeats Steps $1 \& 2$.

## Stochastic proximal gradient algorithm with variance reduction

## Stochastic proximal gradient algorithm with variance reduction (Prox-SVRG) [13]

1. Choose $\widetilde{\mathbf{x}}^{0} \in \mathbb{R}^{p}$ as a starting point and $\gamma>0$ and $n \in \mathbb{N}_{+}$.
2. For $s=0,1,2 \cdots$, perform:

2a. $\widetilde{\mathbf{x}}=\widetilde{\mathbf{x}}^{s}, \quad \widetilde{\mathbf{v}}=\nabla f(\widetilde{\mathbf{x}}), \quad \mathbf{x}_{0}=\widetilde{\mathbf{x}}$.
2b. For $k=0,1, \cdots n-1$, perform:

$$
\left\{\begin{array}{l}
\text { Pick } i_{k} \in\{1, \ldots, m\} \text { uniformly at random }  \tag{16}\\
\mathbf{r}_{k}=\nabla f_{i_{k}}\left(\mathbf{x}_{k}\right)-\nabla f_{i_{k}}(\widetilde{\mathbf{x}})+\widetilde{\mathbf{v}} \\
\mathbf{x}^{k+1}:=\operatorname{prox}_{\gamma g}\left(\mathbf{x}^{k}-\gamma \mathbf{r}_{k}\right)
\end{array}\right.
$$

2c. Update $\widetilde{\mathbf{x}}^{s}=\frac{1}{n} \sum_{j=0}^{n-1} \mathbf{x}^{j}$.

## Common features

- The Prox-SVRG method uses a multistage scheme to reduce the variance of the stochastic gradient $\mathbf{r}_{k}$ where $\mathbf{x}_{k}$ and $\widetilde{\mathbf{x}}^{s}$ tend to $\mathbf{x}_{\star}$.
- Learning rate is not necessary tend to 0 .
- Each stage, Prox-SVRG uses $m+2 n$ component gradient evaluations: $m$ for the full gradient at the beginning of each stage, and $2 n$ for each of the $n$ proximal stochastic gradient steps.

## Convergence analysis

## Assumption A5.

(i) $F=f+g$ is $\mu$-strongly convex
(ii) The learning rate $0<\gamma<1 /\left(4 L_{\max }\right)$.
(iii) $n$ is large enough such that

$$
\kappa=\frac{1}{\mu \gamma\left(1-4 \gamma L_{\max }\right) n}+\frac{4 \gamma L_{\max }(n+1)}{\left(1-4 \gamma L_{\max }\right) n}<1 .
$$

## Theorem

## Assumptions:

- The sequence $\left\{\widetilde{\mathbf{x}^{s}}\right\}_{k \geq 0}$ is generated by Prox-SVRG.
- Assumption A5. is satisfied.

Conclusion: Linear convergence is obtained:

$$
\mathbb{E} F\left(\widetilde{\mathbf{x}^{s}}\right)-F\left(\mathbf{x}^{\star}\right) \leq \kappa^{s}\left(F\left(\widetilde{\mathbf{x}^{0}}\right)-F\left(\mathbf{x}^{\star}\right)\right) .
$$

## Convergence analysis

## Assumption A5.

(i) $F=f+g$ is $\mu$-strongly convex
(ii) The learning rate $0<\gamma<1 /\left(4 L_{\max }\right)$.
(iii) $n$ is large enough such that

$$
\kappa=\frac{1}{\mu \gamma\left(1-4 \gamma L_{\max }\right) n}+\frac{4 \gamma L_{\max }(n+1)}{\left(1-4 \gamma L_{\max }\right) n}<1 .
$$

## Theorem

## Assumptions:

- The sequence $\left\{\mathbf{x}^{k}\right\}_{k \geq 0}$ is generated by Prox-SVRG.
- Assumption A5. is satisfied.

Conclusion: For any $\epsilon>0$ and $\delta \in(0,1): P\left(F\left(\widetilde{\mathbf{x}^{s}}\right)-F\left(\mathbf{x}^{\star}\right) \leq \epsilon\right) \geq 1-\delta$ whenever

$$
s \geq \log \left(\frac{F\left(\widetilde{\mathbf{x}^{0}}\right)-F\left(\mathbf{x}^{\star}\right)}{\delta \epsilon}\right) / \log (1 / \kappa)
$$

## Choice of $\gamma$ and $n$, and complexity

## Chose $\gamma$ and $n$ such that $\kappa \in(0,1)$ :

For example

$$
\gamma=0.1 / L \max , n=100\left(L_{\max } / \mu\right) \Longrightarrow \kappa \approx 5 / 6
$$

## Complexity

$$
\mathbb{E} F\left(\widetilde{\mathbf{x}^{s}}\right)-F\left(\mathbf{x}^{\star}\right) \leq \varepsilon \text { when } s \geq \log \left(\kappa^{-1}\right) \log \left(\left(F\left(\widetilde{\mathbf{x}^{0}}\right)-F\left(\mathbf{x}^{\star}\right)\right) / \epsilon\right)
$$

Since at each stage needs $m+2 n$ component gradient evaluations, with $n=\mathcal{O}\left(L_{\text {max }} / \mu\right)$, we get the overall complexity is

$$
\mathcal{O}\left(\left(m+L_{\max } / \mu\right) \log (1 / \epsilon)\right)
$$

## Example: $\ell_{1}$-regularized least squares revisited- Numerical test

## SPG: $\gamma_{t}=100 /(100+t)$ and Prox-SVRG: $\gamma=0.1 / L_{\max }$

## *Variance reduction techniques: SAGA

## Stochastic Average Gradient (SAGA) [16]

1a. Choose $\tilde{\mathbf{x}}_{i}^{0}=\mathbf{x}^{0} \in \mathbb{R}^{p}, \forall i, 0 \neq q \in \mathbb{N}$ and stepsize $\gamma>0$.
1b. Store $\nabla f_{i}\left(\tilde{\mathbf{x}}_{i}^{0}\right)$ in a table data-structure with length $m$.
2. For $k=0,1 \ldots$ perform:

2a. pick $i_{k} \in\{1, \ldots, m\}$ uniformly at random
2b. Take $\tilde{\mathbf{x}}_{i_{k}}^{k+1}=\mathbf{x}^{k}$, store $\nabla f_{i_{k}}\left(\tilde{\mathbf{x}}_{i_{k}}^{k+1}\right)$ in the table and leave other entries the same.
2c. $v_{k}=\nabla f_{i_{k}}\left(\mathbf{x}^{k}\right)-\nabla f_{i_{k}}\left(\tilde{\mathbf{x}}_{i_{k}}^{k}\right)+\frac{1}{m} \sum_{i=1}^{m} \nabla f_{i}\left(\tilde{\mathbf{x}}_{i}^{k}\right)$
3. $\mathbf{x}^{k+1}=\operatorname{prox}_{\gamma g}\left(\mathbf{x}^{k}-\gamma v_{k}\right)$

## Recipe:

In a cycle of $q$ iterations:

- Store last gradient evaluated at each datapoint.
- Previous gradient for datapoint $j$ is $\nabla f_{j}\left(\tilde{\mathbf{x}}_{j}^{k}\right)$.
- Perform $q$ SG-iterations with the following stochastic gradient

$$
v_{k}=\nabla f_{i_{k}}\left(\mathbf{x}^{k}\right)-\nabla f_{i_{k}}\left(\tilde{\mathbf{x}}_{i_{k}}^{k}\right)+\sum_{i=1}^{n} \nabla f_{i}\left(\tilde{\mathbf{x}}_{i}^{k}\right)
$$

## *Convergence of SAGA

$$
F^{\star}:=\min _{\mathbf{x} \in \mathbb{R}^{p}}\left\{(f(\mathbf{x})+g(\mathbf{x})):=\frac{1}{m} \sum_{i=1}^{m} f_{i}(\mathbf{x})+g(\mathbf{x})\right\} .
$$

## Theorem (Convergence of SAGA [16])

Set $L_{\text {max }}=\max _{1 \leq i \leq m} L_{i}$, where $L_{i}$ is Lipschitz constant of $\nabla f_{i}$. Suppose that $f$ is $\mu$-strongly convex and that the stepsize is $\gamma=\frac{1}{2(\mu n+L)}$ with

$$
\begin{gathered}
\rho=1-\frac{\mu}{2(\mu n+L)}<1, \\
C=\left\|\mathbf{x}^{0}-\mathbf{x}^{\star}\right\|^{2}+\frac{n}{\mu n+L}\left[f\left(\mathbf{x}^{0}\right)-\left\langle\nabla f\left(\mathbf{x}^{\star}\right), \mathbf{x}^{0}-\mathbf{x}^{\star}\right\rangle-f\left(\mathbf{x}^{\star}\right)\right]
\end{gathered}
$$

Then

$$
\mathbb{E}\left[\left\|\mathbf{x}^{k}-\mathbf{x}^{\star}\right\|^{2}\right] \leq \rho^{k} C .
$$

- Allows the constant step-size.
- Obtains linear rate convergence.

Recall that in Lecture 7 we mentioned SARAH. However, how to extend SARAH to composite optimization is open.
